Constrained Join Proxy for Bootstrapping Protocols
draft-ietf-anima-constrained-join-proxy-00

Abstract

This document defines a protocol to securely assign a pledge to a domain, represented by an EST server, using an intermediary node between pledge and EST server. This intermediary node is known as a "constrained Join Proxy".

This document extends the work of [I-D.ietf-anima-bootstrapping-keyinfra] by replacing the Circuit-proxy by a stateless/stateful constrained (CoAP) Join Proxy. It transports join traffic from the pledge to the Registrar without requiring per-client state.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 1, 2021.

1. Introduction

Enrolment of new nodes into networks with enrolled nodes present is described in [I-D.ietf-anima-bootstrapping-keyinfra] ("BRSKI") and makes use of Enrolment over Secure Transport (EST) [RFC7030] with [RFC8366] vouchers to securely enroll devices. BRSKI connects new devices ("pledges") to extended EST servers ("Registrars") via a Join Proxy.

The specified solutions use https and may be too large in terms of code space or bandwidth required for constrained devices. Constrained devices possibly part of constrained networks [RFC7228] typically implement the IPv6 over Low-Power Wireless personal Area Networks (6LoWPAN) [RFC4944] and Constrained Application Protocol (CoAP) [RFC7252].

CoAP can be run with the Datagram Transport Layer Security (DTLS) [RFC6347] as a security protocol for authenticity and confidentiality of the messages. This is known as the "coaps" scheme. A constrained version of EST, using Coap and DTLS, is described in [I-D.ietf-ace-coap-est]. The {I-D.ietf-anima-constrained-voucher} describes the BRSKI extensions to the EST server.

DTLS is a client-server protocol relying on the underlying IP layer to perform the routing between the DTLS Client and the DTLS Server. However, the new "joining" device will not be IP routable until it is authenticated to the network. A new "joining" device can only initially use a link-local IPv6 address to communicate with a neighbour node using neighbour discovery [RFC6775] until it receives the necessary network configuration parameters. However, before the device can receive these configuration parameters, it needs to authenticate itself to the network to which it connects. IPv6 routing is necessary to establish a connection between joining device and the extended EST server.

A DTLS connection is required between Pledge and EST server.

This document specifies a new form of Join Proxy and protocol to act as intermediary between joining device and EST server to establish a connection between joining device and EST server.

This document is very much inspired by text published earlier in [I-D.kumar-dice-dtls-relay]. [I-D.richardson-anima-state-for-joinrouter] outlined the various options for building a join proxy. [I-D.ietf-anima-bootstrapping-keyinfra] adopted only the Circuit Proxy method (1), leaving the other methods as future work. This document standardizes the CoAP/DTLS (method 4).

2. Terminology

The following terms are defined in [RFC8366], and are used identically as in that document: artifact, imprint, domain, Join Registrar/Coordinator (JRC), Manufacturer Authorized Signing Authority (MASA), pledge, Trust of First Use (TOFU), and Voucher.

3. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

4. Join Proxy functionality

As depicted in the Figure 1, the joining Device, or pledge (P), in an LLN mesh can be more than one hop away from the EST server (E) and not yet authenticated into the network.

In this situation, it can only communicate one-hop to its nearest neighbour, the Join Proxy (J) using their link-local IPv6 addresses. However, the Pledge (P) needs to communicate with end-to-end security with a Registrar hosting the EST server (E) to authenticate and get the relevant system/network parameters. If the Pledge (P) initiates a DTLS connection to the EST server whose IP address has been pre-configured, then the packets are dropped at the Join Proxy (J) since the Pledge (P) is not yet admitted to the network or there is no IP routability to Pledge (P) for any returned messages.

Figure 1: multi-hop enrolment.

Without routing the Pledge (P) cannot establish a secure connection to the EST server (E) in the network assuming appropriate credentials are exchanged out-of-band, e.g. a hash of the Pledge (P)'s raw public key could be provided to the EST server (E).

Furthermore, the Pledge (P) may be unaware of the IP address of the EST server (E) to initiate a DTLS connection and perform authentication.

To overcome the problems with non-routability of DTLS packets and/or discovery of the destination address of the EST Server to contact, the Join Proxy is introduced. This Join Proxy functionality is configured into all authenticated devices in the network which may act as the Join Proxy for newly joining nodes. The Join Proxy allows for routing of the packets from the Pledge using IP routing to the intended EST Server.

5. Join Proxy specification

A Join Proxy can operate in two modes:

- o Statefull mode
- o Stateless mode

5.1. Statefull Join Proxy

In stateful mode, the joining node forwards the DTLS messages to the EST server.

Assume that the Pledge does not know the IP address of the EST Server it needs to contact. In that situation, the Join Proxy must know the (configured or discovered) IP address of a EST server. (Discovery can be based upon [I-D.ietf-anima-bootstrapping-keyinfra] section 4.3, or via DNS-SD service discovery [RFC6763]) The Pledge initiates its request as if the Join Proxy is the intended EST server. The Join Proxy changes the IP packet (without modifying the DTLS message) by modifying both the source and destination addresses to forward the message to the intended EST Server. The Join Proxy maintains a 4-tuple array to translate the DTLS messages received from the EST Server and forward it to the EST Client. This is a form of Network Address translation, where the Join Proxy acts as a forward proxy. In Figure 2 the various steps of the message flow are shown, with 5684 being the standard coaps port:

EST Client (P)	Join Proxy (J)	EST Server (E)	Message	
			Src_IP:port	Dst_IP:port
			IP_P:p_P	IP_Ja:5684
			IP_Jb:p_Jb	IP_E:5684
			IP_E:5684	IP_Jb:p_Jb
		:		
		:	IP_Ja:5684	IP_P:p_P
		:	:	:
		:	:	:
		:	IP_P:p_P	IP_Ja:5684
			IP_Jb:p_Jb	IP_E:5684
			IP_E:5684	IP_Jb:p_Jb
			IP_Ja:5684	IP_P:p_P
		:	:	:

IP_P:p_P = Link-local IP address and port of Pledge (DTLS Client)
 IP_E:5684 = Global IP address and coaps port of EST Server
 IP_Ja:5684 = Link-local IP address and coaps port of Join Proxy
 IP_Jb:p_Rb = Global IP address and port of Join proxy

Figure 2: constrained statefull joining message flow with EST server address known to Join Proxy.

5.2. Stateless Join Proxy

The Join Proxy is stateless to minimize the requirements on the constrained Join Proxy device. Stateless operation requires no memory in the Join Proxy device, but may also reduce the CPU impact as the device does not need to search through a state table.

When a client joining device attempts a DTLS connection to the EST server, it uses its link-local IP address as its IP source address. This message is transmitted one-hop to a neighbouring (join proxy) node. Under normal circumstances, this message would be dropped at the neighbour node since the joining device is not yet IP routable or it is not yet authenticated to send messages through the network. However, if the neighbour device has the Join Proxy functionality enabled, it routes the DTLS message to a specific EST server. Additional security mechanisms need to exist to prevent this routing functionality being used by rogue nodes to bypass any network authentication procedures.

If an untrusted DTLS Client that can only use link-local addressing wants to contact a trusted end-point EST server, it sends the DTLS message to the Join Proxy.

The Join Proxy extends this message into a new type of message called Join ProxY (JPY) message and sends it on to the EST server.

The JPY message payload consists of two parts:

- o Header (H) field: consisting of the source link-local address and port of the Pledge (P), and
- o Contents (C) field: containing the original DTLS message.

On receiving the JPY message, the EST server retrieves the two parts.

The EST server transiently stores the Header field information. The EST server uses the Contents field to execute the EST server functionality. However, when the EST server replies, it also extends its DTLS message with the header field in a JPY message and sends it back to the Join Proxy. The EST server SHOULD NOT assume that it can decode the Header Field, it should simply repeat it when responding. The Header contains the original source link-local address and port of the DTLS Client from the transient state stored earlier (which can now be discarded) and the Contents field contains the DTLS message.

On receiving the JPY message, the Join Proxy retrieves the two parts. It uses the Header field to route the DTLS message retrieved from the Contents field to the Pledge.

The Figure 3 depicts the message flow diagram:

IP_P:p_P = Link-local IP address and port of the Pledge
 IP_E:p_Ea = Global IP address and join port of EST Server
 IP_Ja:p_Ja = Link-local IP address and join port of Join Proxy
 IP_Jb:p_Jb = Global IP address and port of Join Proxy

JPY[H(),C()] = Join Proxy message with header H and content C

Figure 3: constrained stateless joining message flow.

5.3. Stateless Message structure

The JPY message is constructed as a payload with media-type application/multipart-core specified in [I-D.ietf-core-multipart-ct].

Header and Contents fields use different media formats:

1. header field: application/cbor containing a CBOR array [RFC7049] with the pledge IPv6 Link Local address as a 16-byte binary value, the pledge's UDP port number, if different from 5684, as a CBOR integer, and the proxy's ifindex or other identifier for the physical port on which the pledge is connected. Header is not DTLS encrypted.
2. Content field: Any of the media types specified in [I-D.ietf-ace-coap-est] and [I-D.ietf-anima-constrained-voucher] dependent on the function that is requested:

- * application/pkcs7-mime; smime-type=server-generated-key
- * application/pkcs7-mime; smime-type=certs-only
- * application/voucher-cms+cbor
- * application/voucher-cose+cbor
- * application/pkcs8
- * application/csrattrs
- * application/pkcs10
- * application/pkix-cert

(XXX- add CDDL for CBOR array above)

The content fields are DTLS encrypted. In CBOR diagnostic notation the payload JPY[H(IP_P:p_P), with cf is content-format of DTLS-content, will look like:

```
[ 60, [IP_p, p_P, ident]
  cf, h'DTLS-content']
```

Examples are shown in Appendix A.

6. Comparison of stateless and statefull modes

The stateful and stateless mode of operation for the Join Proxy have their advantages and disadvantages. This section should enable to make a choice between the two modes based on the available device resources and network bandwidth.

Properties	Stateful mode	Stateless mode
State Information	The Join Proxy needs additional storage to maintain mapping between the address and port number of the pledge and those of the EST server.	No information is maintained by the Join Proxy
Packet size	The size of the forwarded message is the same as the original message.	Size of the forwarded message is bigger than the original, it includes additional source and destination addresses.
Specification complexity	The Join Proxy needs additional functionality to maintain state information, and modify the source and destination addresses of the DTLS handshake messages	New JPY message to encapsulate DTLS message The EST server and the Join Proxy have to understand the JPY message in order to process it.

Figure 4: Comparison between stateful and stateless mode

7. Discovery

It is assumed that Join Proxy seamlessly provides a coaps connection between Pledge and coaps EST server. In particular this section replaces section 4.2 of [I-D.ietf-anima-bootstrapping-keyinfra].

The discovery follows two steps:

1. The pledge is one hop away from the EST server. The pledge discovers the link-local address of the EST_server as described in {I-D.ietf-ace-coap-est}. From then on, it follows the BRSKI process as described in {I-D.ietf-ace-coap-est}, using link-local addresses.
2. The pledge is more than one hop away from a relevant EST server, and discovers the link-local address of a Join Proxy. The pledge then follows the BRSKI procedure using the link-local address of the Join Proxy.

Once a pledge is enrolled, it may function as Join Proxy. The Join Proxy functions are advertised as described below. Usually, the Join

Proxy functions are offered via a "join" port, and not the standard coaps port. The Join Proxy MUST show the join port number when replying to the .well-known/core request addressed to the standard coap/coaps port.

Three discovery cases are discussed: coap discovery, 6tisch discovery and GRASP discovery.

7.1. Pledge discovery of Join Proxy

The pledge and Join Proxy are assumed to communicate via Link-Local addresses.

7.1.1. CoAP discovery

The discovery of the coaps EST server, using coap discovery, by the Join Proxy follows section 6 of [I-D.ietf-ace-coap-est].

7.1.2. Autonomous Network

In the context of autonomous networks, the Join Proxy uses the DULL GRASP M_FLOOD mechanism to announce itself. Section 4.1.1 of [I-D.ietf-anima-bootstrapping-keyinfra] discusses this in more detail. The Registrar announces itself using ACP instance of GRASP using M_FLOOD messages. Autonomous Network Join Proxies MUST support GRASP discovery of EST server as described in section 4.3 of [I-D.ietf-anima-bootstrapping-keyinfra] .

7.1.3. 6tisch discovery

The discovery of EST server by the pledge uses the enhanced beacons as discussed in [I-D.ietf-6tisch-enrollment-enhanced-beacon].

7.2. Join Proxy discovers EST server

7.2.1. Autonomous Network

The pledge MUST listen for GRASP M_FLOOD [I-D.ietf-anima-grasp] announcements of the objective: "AN_Proxy". See section Section 4.1.1 [I-D.ietf-anima-bootstrapping-keyinfra] for the details of the objective.

7.2.2. CoAP discovery

In the context of a coap network without Autonomous Network support, discovery follows the standard coap policy. The Pledge can discover a Join Proxy by sending a link-local multicast message to ALL CoAP Nodes with address FF02::FD. Multiple or no nodes may respond. The

handling of multiple responses and the absence of responses follow section 4 of [I-D.ietf-anima-bootstrapping-keyinfra].

The presence and location of (path to) the Join Proxy resource are discovered by sending a GET request to `"/.well-known/core"` including a resource type (rt) parameter with the value `"brski-proxy"` [RFC6690]. Upon success, the return payload will contain the root resource of the Join Proxy resources. It is up to the implementation to choose its root resource; throughout this document the example root resource `/jp` is used. The example below shows the discovery of the presence and location of Join Proxy resources.

```
REQ: GET coap://[FF02::FD]/.well-known/core?rt=brski-proxy
```

```
RES: 2.05 Content
```

```
<coaps://[IP_address]:jp-port/jp>; rt="brski-proxy";ct=62
```

Port numbers are assumed to be the default numbers 5683 and 5684 for coap and coaps respectively (sections 12.6 and 12.7 of [RFC7252] when not shown in the response. Discoverable port numbers are usually returned for Join Proxy resources in the `<href>` of the payload (see section 5.1 of [I-D.ietf-ace-coap-est]).

8. Security Considerations

It should be noted here that the contents of the CBOR map used to convey return address information is not protected. However, the communication is between the Proxy and a known registrar are over the already secured portion of the network, so are not visible to eavesdropping systems.

All of the concerns in [I-D.ietf-anima-bootstrapping-keyinfra] section 4.1 apply. The pledge can be deceived by malicious AN_Proxy announcements. The pledge will only join a network to which it receives a valid [RFC8366] voucher.

If the proxy/Registrar was not over a secure network, then an attacker could change the cbor array, causing the pledge to send traffic to another node. If the such scenario needed to be supported, then it would be reasonable for the Proxy to encrypt the CBOR array using a locally generated symmetric key. The Registrar would not be able to examine the result, but it does not need to do so. This is a topic for future work.

9. IANA Considerations

This document needs to create a registry for key indices in the CBOR map. It should be given a name, and the amending formula should be IETF Specification.

9.1. Resource Type registry

This specification registers a new Resource Type (rt=) Link Target Attributes in the "Resource Type (rt=) Link Target Attribute Values" subregistry under the "Constrained RESTful Environments (CoRE) Parameters" registry.

rt="brski-proxy". This EST resource is used to query and return the supported EST resource of a Join Proxy placed between Pledge and EST server.

Appendix A. Stateless Proxy payload examples

Examples need to be redone

Examples are extensions of two examples shown in [I-D.ietf-ace-coap-est]. The following content formats are used:

- o 60: application/cbor
- o 62: application/multipart
- o 281: application/pkcs7-mime; smime-type=certs-only
- o 284: application/pkcs8
- o 286: application/pkcs10

For presentation purposes the payloads are abbreviated as follows:

cacrts request payload:

<cacrts request payload> = <empty>

cacrts response payload:

```

<cacrts response payload> =

A.1. cacerts

The request from Join Proxy to EST server looks like:

```

Get coaps://192.0.2.1/est/crts
(Accept: 62)
(Content-format: 62)
payload =
  82                                     # array(2)
  18 3C                                  # unsigned(60)
  83                                     # array(3)
  69                                     # text(9)
      464538303A3A414238 # "FE80::AB8"
  19 237D                               # unsigned(9085)
  65                                     # text(5)
      6964656E74         # "ident"

```

In CBOR Diagnostic:

```
payload = [60, ["FE80::AB8", 9085, "ident"]]
```

The response will then be:

```
2.05 Content
(Content-format: 62)
  Payload =
84                                     # array(4)
18 3C                                 # unsigned(60)
83                                     # array(3)
69                                     # text(9)
    464538303A3A414238                # "FE80::AB8"
19 237D                               # unsigned(9085)
65                                     # text(5)
    6964656E74                        # "ident"
19 0119                               # unsigned(281)
59 027F                               # bytes(639)
<cacrts response payload>
]
```

In CBOR diagnostic:

```
payload = [60, ["FE80::AB8", 9085, "ident"],
           62, h'<cacrts response payload>']
```

A.2. serverkeygen

The request from Join Proxy to EST server looks like:

```
Get coaps://192.0.2.1/est/skg
(Accept: 62)
(Content-Format: 62)
  Payload =
83                                     # array(4)
18 3C                                 # unsigned(60)
83                                     # array(3)
69                                     # text(9)
    464538303A3A414238                # "FE80::AB8"
19 237D                               # unsigned(9085)
65                                     # text(5)
    6964656E74                        # "ident"
19 011E                               # unsigned(286)
58 D2                                 # bytes(210)
<serverkeygen request payload>
```

In CBOR diagnostic:

```
payload = [60, ["FE80::AB8", 9085, "ident"],
           286, h'<serverkeygen request payload>']
```

The response will then be:

```
2.05 Content
(Content-format: 62)
  Payload =
83                                     # array(4)
18 3C                                 # unsigned(60)
83                                     # array(3)
69                                     # text(9)
    464538303A3A414238                # "FE80::AB8"
19 237D                               # unsigned(9085)
65                                     # text(5)
    6964656E74                        # "ident"
19 011E                               # unsigned(286)
59 0269                               # bytes(617)
<serverkeygen response payload>
```

In CBOR diagnostic:

```
payload = [60, ["FE80::AB8", 9085, "ident"],
           286, h'<serverkeygen response payload>']
```
