Mutual Authentication Protocol for HTTP: KAM3-based Cryptographic Algorithms draft-ietf-httpauth-mutual-algo-00

Abstract

This document specifies some cryptographic algorithms which will be used for the Mutual user authentication method for the Hyper-text Transport Protocol (HTTP).

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as “work in progress.”

This Internet-Draft will expire on January 5, 2015.

Code Components extracted from this document must include Simplified BSD License text as described in Section 4.e of the Trust Legal Provisions and are provided without warranty as described in the Simplified BSD License.

Table of Contents

1. Introduction

This document specifies some algorithms for Mutual authentication protocol for Hyper-Text Transport Protocol (HTTP) [I-D.ietf-httpauth-mutual]. The algorithms are based on so-called "Augumented Password-based Authenticated Key Exchange" (Augumented PAKE) techniques. In particular, it uses one of three key exchange algorithm defined in the ISO 11770-4: "Key management - Mechanisms based on weak secrets" [ISO.11770-4.2006] as a basis.

In very brief summary, the Mutual authentication protocol exchanges four values, K_{c1}, K_{s1}, VK_c and VK_s, to perform authenticated key exchanges, using the password-derived secret pi and its "augumented version" J(pi). This document defines the set of functions K_{c1}, K_{s1}, and J for a specific algorithm family.

Please note that, from the view of cryptographic literatures, the original functionality of Augumented PAKE is separated into the functions K_{c1} and K_{s1} defined in this draft, and the functions VK_c and VK_s defined in Section 11 of [I-D.ietf-httpauth-mutual] as "default functions". For the purpose of security analysis, please also refer to these functions.

1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The term "natural numbers" refers to the non-negative integers (including zero) throughout this document.

This document treats target (codomain) of hash functions to be octet strings. The notation INT(H(s)) gives a natural-number output of hash function H applied to string s.

2. Authentication Algorithms

This document specifies only one family of the authentication algorithm. The family consists of four authentication algorithms, which only differ in their underlying mathematical groups and security parameters. The algorithms do not add any additional parameters. The tokens for these algorithms are

- iso-kam3-dl-2048-sha256: for the 2048-bit discrete-logarithm setting with the SHA-256 hash function.
- iso-kam3-dl-4096-sha512: for the 4096-bit discrete-logarithm setting with the SHA-512 hash function.
- iso-kam3-ec-p256-sha256: for the 256-bit prime-field elliptic-curve setting with the SHA-256 hash function.
- iso-kam3-ec-p521-sha512: for the 521-bit prime-field elliptic-curve setting with the SHA-512 hash function.

For discrete-logarithm settings, the underlying groups are the 2048-bit and 4096-bit MODP groups defined in [RFC3526], respectively. See Appendix A for the exact specifications of the groups and associated parameters. The hash functions H are SHA-256 for the 2048-bit group and SHA-512 for the 4096-bit group, respectively, defined in FIPS PUB 180-2 [FIPS.180-2.2002]. The hash iteration count nIterPi is 16384. The representation of the parameters kc1, ks1, vkc, and vks is base64-fixed-number.

For the elliptic-curve settings, the underlying groups are the elliptic curves over the prime fields P-256 and P-521, respectively, specified in the appendix D.1.2 of FIPS PUB 186-3 [FIPS.186-3.2009] specification. The hash functions H, which are referenced by the core document, are SHA-256 for the P-256 curve and SHA-512 for the P-521 curve, respectively. The hash iteration count nIterPi is 16384. The representation of the parameters kc1, ks1, vkc, and vks is hex-fixed-number.

[[Editorial Note: remove before submission] We should take a care on recent hot discussion topic on the choice of elliptic curves for cryptography. If the discussion leads to some recommendation on "default choice of curves" before publishing this document as an RFC, the authors will reflect that change to the paragraph above (reference to FIPS 186-3). If not, we may need to update this document with specifying a new set of algorithm identifier tokens for use of new curves.]

Note: This algorithm is based on the Key Agreement Mechanism 3 (KAM3) defined in Section 6.3 of ISO/IEC 11770-4 [ISO.11770-4.2006] with a few modifications/improvements. However, implementers should use this document as the normative reference, because the algorithm has been changed in several minor details as well as major improvements.

2.1. Support Functions and Notations

The algorithm definitions use several support functions and notations defined below:

The integers in the specification are in decimal, or in hexadecimal when prefixed with "0x".

The functions named octet(), OCTETS(), and INT() are those defined in the core specification [I-D.ietf-httpauth-mutual].

Note: The definition of OCTETS() is different from the function GE2OS_x in the original ISO specification, which takes the shortest representation without preceding zeros.

All of the algorithms defined in this specification use the default functions defined in the core specification (defined in Section 11 of [I-D.ietf-httpauth-mutual]) for computing the values pi, VK_c and VK_s.

2.2. Functions for Discrete-Logarithm Settings

In this section, an equation (x / y mod z) denotes a natural number w less than z that satisfies (w * y) mod z = x mod z.

For the discrete-logarithm, we refer to some of the domain parameters by using the following symbols:

- q: for "the prime" defining the MODP group.
- g: for "the generator" associated with the group.
- r: for the order of the subgroup generated by g.

The function J is defined as

J(pi) = g^(pi) mod q.

The value of K_{c1} is derived as

K_{c1} = g^(S_{c1}) mod q,

where S_{c1} is a random integer within range [1, r-1] and r is the size of the subgroup generated by g. In addition, S_{c1} MUST be larger than log(q)/log(g) (so that g^(S_{c1}) > q).

The value of K_{c1} SHALL satisfy 1 < K_{c1} < q-1. The server MUST check this condition upon reception.

Let an intermediate value t_1 be

t_1 = INT(H(octet(1) | OCTETS(K_{c1}))),

the value of K_{s1} is derived from J(pi) and K_{c1} as:

K_{s1} = (J(pi) * K_{c1}^(t_1))^(S_{s1}) mod q

where S_{s1} is a random number within range [1, r-1]. The value of K_{s1} MUST satisfy 1 < K_{s1} < q-1. If this condition is not held, the server MUST retry using another value for S_{s1}. The client MUST check this condition upon reception.

Let an intermediate value t_2 be

$t_2 = \mathrm{INT}(H(\mathrm{octet}(2) \mid \mathrm{OCTETS}(K_{c1}) \mid \mathrm{OCTETS}(K_{s1})))$,

the value z on the client side is derived by the following equation:

$z = K_{s1}$^(($S_{c1} + t_2$) / ($S_{c1} * t_1$ + pi) mod r) mod q.

The value z on the server side is derived by the following equation:

$z = (K_{c1} * g$^(t_2))^(S_{s1}) mod q.

(Note: the original ISO specification contained a message pair containing verification of value z along with the "transcript" of the protocol exchange. The functionality of this kind is contained in the functions VK_c and VK_s.)

2.3. Functions for Elliptic-Curve Settings

For the elliptic-curve setting, we refer to some of the domain parameters by the following symbols:

- q: for the prime used to define the group.
- G: for the defined point called the generator.
- r: for the order of the subgroup generated by G.

The function P(p) converts a curve point p into an integer representing point p, by computing x * 2 + (y mod 2), where (x, y) are the coordinates of point p. P'(z) is the inverse of function P, that is, it converts an integer z to a point p that satisfies P(p) = z. If such p exists, it is uniquely defined. Otherwise, z does not represent a valid curve point. The operator + indicates the elliptic-curve group operation, and the operation [x] * p denotes an integer-multiplication of point p: it calculates p + p + ... (x times) ... + p. See the literatures on elliptic-curve cryptography for the exact algorithms used for those functions (e.g. Section 3 of [RFC6090], which uses different notations, though.) 0_E represents the infinity point. The equation (x / y mod z) denotes a natural number w less than z that satisfies (w * y) mod z = x mod z.

The function J is defined as

J(pi) = [pi] * G.

The value of K_{c1} is derived as

$K_{c1} = P(K_{c1}')$, where $K_{c1}' = [S_{c1}] * G$,

where S_{c1} is a random number within range [1, r-1]. The value of K_{c1} MUST represent a valid curve point, and K_{c1}' SHALL NOT be 0_E. The server MUST check this condition upon reception.

Let an intermediate integer t_1 be

$t_1 = \mathrm{INT}(H(\mathrm{octet}(1) \mid \mathrm{OCTETS}(K_{c1})))$,

the value of K_{s1} is derived from J(pi) and $K_{c1}' = P'(K_{c1})$ as:

$K_{s1} = P([S_{s1}] * (J(pi) + [t_1] * K_{c1}'))$,

where S_{s1} is a random number within range [1, r-1]. The value of K_{s1} MUST represent a valid curve point and satisfy $[4] * P'(K_{s1}) <> 0_E$. If this condition is not satisfied, the server MUST retry using another value for S_{s1}. The client MUST check this condition upon reception.

Let an intermediate integer t_2 be

$t_2 = INT(H(octet(2) | OCTETS(K_{c1}) | OCTETS(K_{s1})))$,

the value z on the client side is derived by the following equation:

$z = P([(S_{c1} + t_2) / (S_{c1} * t_1 + pi) \bmod r] * P'(K_{s1}))$.

The value z on the server side is derived by the following equation:

$z = P([S_{s1}] * (P'(K_{c1}) + [t_2] * G))$.

3. IANA Considerations

Four tokens iso-kam3-dl-2048-sha256, iso-kam3-dl-4096-sha512, iso-kam3-ec-p256-sha256 and iso-kam3-ec-p521-sha512 shall be allocated and registered according to the provision of the core documentation when this document is promoted to an RFC.

Note: More formal declarations will be added in the future drafts to meet the RFC 5226 requirements.

4. Security Considerations

Refer the corresponding section of the core specification for algorithm-independent, generic considerations.

- All random numbers used in these algorithms MUST be at least cryptographically computationally secure against forward and backward guessing attacks.
- Computation times of all numerical operations on discrete-logarithm group elements and elliptic-curve points MUST be normalized and made independent of the exact values, to prevent timing-based side-channel attacks.

The usual construction of authenticated key exchange algorithms are build from a key-exchange period and a key verification period, and the latter usually involving some kind of exchange transaction to be verified, to avoid security risks or vulnerabilities caused from mixing of values from two or more key exchanges. In the design of the algorithms in this document, such a functionality is defined in generalized manner in the core specification [I-D.ietf-httpauth-mutual] (see definitions of VK_c and VK_s). If any attempts to reuse the algorithm defined above with any other protocols exist, care MUST be taken on that aspect.

5. Notice on intellectual properties

The National Institute of Advanced Industrial Science and Technology (AIST) and Yahoo! Japan, Inc. has jointly submitted a patent application on the protocol proposed in this documentation to the Patent Office of Japan. The patent is intended to be open to any implementors of this protocol and its variants under non-exclusive royalty-free manner. For the details of the patent application and its status, please contact the author of this document.

The elliptic-curve based authentication algorithms might involve several existing third-party patents. The authors of the document take no position regarding the validity or scope of such patents, and other patents as well.

Appendix B. (Informative) Derived Numerical Values

This section provides several numerical values for implementing this protocol, derived from the above specifications. The values shown in this section are for informative purposes only.

	dl-2048	**dl-4096**	**ec-p256**	**ec-p521**	
Size of K_{c1} etc.	2048	4096	257	522	(bits)
hSize, Size of H(...)	256	512	256	512	(bits)
length of OCTETS(K_{c1}) etc.	256	512	33	66	(octets)
length of kc1, ks1 param. values.	344 *	684 *	66	132	(octets)
length of vkc, vks param. values.	44 *	88 *	64	128	(octets)
minimum allowed S_{c1}	2048	4096	1	1	

(The numbers marked with an * do not include any enclosing quotation marks.)

Appendix C. (Informative) Draft Change Log

C.1. Changes in HTTPAUTH-WG revision 00

- Added a note on the choice of elliptic curves.

C.2. Changes in HTTPAUTH revision 02

- Added nIterPi parameter to adjust to the changes to the core draft.
- Added a note on the verification of exchange transaction.

C.3. Changes in HTTPAUTH revision 01

- Notation change: integer output of hash function will be notated as INT(H(*)), changed from H(*).

C.4. Changes in revision 02

- Implementation hints in appendix changed (number of characters for base64-fixed-number does not contain double-quotes).

C.5. Changes in revision 01

- Parameter names renamed.
- Some expressions clarified without changing the value.

C.6. Changes in revision 00

The document is separated from the revision 08 of the core documentation.
