Re-keying Mechanisms for Symmetric Keys

draft-irtf-cfrg-re-keying-00

Abstract

This specification contains a description of a variety of methods to increase the lifetime of symmetric keys. It provides external and internal re-keying mechanisms that can be used with such modes of operations as CTR, GCM, CBC, CFB, OFB and OMAC.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on August 31, 2017.

Authors' Addresses

1. Introduction

Common attacks base their success on the ability to get many encryptions under a single key. If encryption is performed under a single key, there is a certain maximum threshold number of messages that can be safely encrypted. These restrictions can come either from combinatorial properties of the used cipher modes of operation (for example, birthday attack [BDJR]) or from particular cryptographic attacks on the used block cipher (for example, linear cryptanalysis [Matsui]). Moreover, most strict restrictions here follow from the need to resist side-channel attacks. The adversary's opportunity to obtain an essential amount of data processed with a single key leads not only to theoretic but also to practical vulnerabilities (see [BL]). Therefore, when the total size of a plaintext processed with a single key reaches threshold values, this key cannot be used anymore and certain procedures with encryption keys are needed.

The most simple and obvious way for overcoming the key lifetimes limitations is a renegotiation of a regular session key. However, this reduces the total performance since it usually entails the frequent use of a public key cryptography.

Another way is to use a transformation of a previously negotiated key. This specification presents the description of such mechanisms and the description of the cases when these mechanisms should be

V*

2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3. Basic Terms and Definitions

This document uses the following terms and definitions for the sets and operations on the elements of these sets:

(xor) exclusive-or of two binary vectors of the same length.

the set of all strings of a finite length (hereinafter referred to as strings), including the empty string;

V_s
the set of all binary strings of length s, where s is a non-negative integer; substrings and string components are enumerated from right to left starting from one;

|X| the bit length of the bit string X;

A|B concatenation of strings A and B both belonging to V^* , i.e., a string in $V_{|A|+|B|}$, where the left substring in $V_{|A|}$ is equal to A, and the right substring in $V_{|B|}$ is equal to B;

Z_{2^n}
 ring of residues modulo 2^n;

Int_s: $V_s \rightarrow Z_{2^s}$ the transformation that maps a string $a = (a_s, ..., a_1)$, a in V_s , into the integer $Int_s(a) = 2^s a_s + ... + 2^a_2 + a_1$;

MSB_i: $V_s \rightarrow V_i$ the transformation that maps the string $a = (a_s, ..., a_1)$ in V_s , into the string MSB_i(a) = (a_s, ..., a_{s-i+1}) in V_i ;

LSB_i: $V_s \rightarrow V_i$ the transformation that maps the string $a = (a_s, ..., a_1)$ in V_s , into the string LSB_i(a) = $(a_i, ..., a_1)$ in V_i ;

Inc_c: V_s -> V_s the transformation that maps the string $a = (a_s, ..., a_1)$ in V_s, into the string Inc_c(a) = MSB_{|a|-c}(a) | Vec_c(Int_c(LSB_c(a)) + 1(mod 2^c)) in V_s;

denotes the string in V_s that consists of s 'a' bits;

$$\label{eq:continuous} \begin{split} E_{K}: \ V_n & \to V_n \\ & \text{the block cipher permutation under the key K in V_k;} \end{split}$$

ceil(x)
 the least integer that is not less than x;

 $\mbox{\bf k}$ the key K size (in bits);

a^s

A plaintext message P and a ciphertext C are divided into b = ceil(m/n) segments denoted as $P = P_1 | P_2 | \dots | P_b$ and $C = C_1 | C_2 | \dots | C_b$, where P_i and P_i are in P_i are in P_i , for P_i and P_i and P_i are in P_i , where P_i are in P_i are in P_i , where P_i are in P_i and P_i are in P_i are in P_i and P_i are in P_i and P_i are in P_i are in P_i and P_i are in P_i and P_i are in $P_$

4. External Re-keying Mechanisms

This section presents an approach to increase the lifetime of negotiated keys after processing a limited number of integral messages. It provides an external parallel and serial re-keying mechanisms (see [AbBell]). These mechanisms use an initial (negotiated) key as a master key, which is never used directly for the data processing but is used for key generation. Such mechanisms operate outside of the base modes of operations and do not change them at all, therefore they are called "external re-keying" in this document.

4.1. Parallel Constructions

The main idea behind external re-keying with parallel construction is presented in Fig.1:

```
Lifetime of a key = L,
maximum message size = m_max.
             m_max
          <---->
      M_{1,1} |=== |
      +--K^1--> . . .
      M_{1,q_1} |======
      M {2,1} |========|
      M_{2,2} |====
K*----|--K^2--> . . .
      M {2,q 2} |=======
      M {t,2} |======== |
  +--K^t--> . . .
```

```
|M_{i,1}| + ... + |M_{i,q_i}| \le L, i = 1, ..., t. Figure 1: External parallel re-keying mechanisms
```

4.1.1. Parallel Construction Based on a KDF on a Block Cipher

ExtParallelC re-keying mechanism is based on a block cipher and is used to generate t keys for t sections as follows:

```
 K^1 \mid K^2 \mid ... \mid K^t = ExtParallelC(K^*, t^*k) = MSB_{t^*k}(E_{K^*}(0) \mid E_{K^*}(1) \mid ... \mid E_{K^*}(J-1)),  where J = ceil(k/n).
```

4.1.2. Parallel Construction Based on HKDF

ExtParallelH re-keying mechanism is based on HMAC-based key derivation function HKDF-Expand, described in [RFC5869], and is used to generate t keys for t sections as follows:

$$K^1 \mid K^2 \mid ... \mid K^t = ExtParallelH(K^*, t^*k) = HKDF-Expand(K^*, label, t^*k),$$

where label is a string (can be a zero-length string) that is defined by a specific protocol.

4.2. Serial Constructions

The main idea behind external re-keying with serial construction is presented in Fig.2:

```
Lifetime of a key = L,
maximum message size = m_max.
               m_max
            <---->
        M_{1,1} |===
        K^* 1 = K^* --- K^1 --> \dots
        M {1,q 1} |======
        M_{2,1} |=========|
        M_{2,2} |====
K* 2 -----K^2--> . . .
        M {2,q 2} |======= |
Ι
       M_{t,2} |========= |
K* t -----K^t--> . . .
```

```
|M_{i,1}| + ... + |M_{i,q_i}| \le L, i = 1, ..., t.
```

Figure 2: External serial re-keying mechanisms

4.2.1. Serial Construction Based on a KDF on a Block Cipher

The key K¹ is calculated using ExtSerialC transformation as follows:

```
\label{eq:Kappa} \begin{split} & K^{a} = ExtSerialC(K^{*}, \, i) = MSB_{k}(E_{K^{*}_{-i}}(0) \mid E_{K^{*}_{-i}}(1) \mid ... \mid E_{K^{*}_{-i}}(J-1)), \\ & \text{where } J = ceil(k/n), \, i = 1, \, ... \, , \, t, \, K^{*}_{-i} \, \text{is calculated as follows:} \\ & K^{*}_{-1} = K^{*}, \\ & K^{*}_{-1} = K^{*}, \\ & K^{*}_{-1} = MSB_{k}(E_{K^{*}_{-i}}(J) \mid E_{K^{*}_{-i}}(J+1) \mid ... \mid E_{K^{*}_{-i}}(2J-1)), \\ & \text{where } i = 1, \, ... \, , \, t\text{-}1. \end{split}
```

4.2.2. Serial Construction Based on HKDF

The key K¹ is calculated using ExtSerialH transformation as follows:

```
K^i = ExtSerialH(K*, i) = HKDF-Expand(K*_i, label1, k),
```

where i = 1, ..., t, HKDF-Expand is an HMAC-based key derivation function, described in [RFC5869], K^*_i is calculated as follows:

```
K^*\_1 = K^*, K^*\_\{j+1\} = HKDF\text{-}Expand(K^*\_j, \ label2, \ k), \ where \ j=1, \ \dots \ , \ t\text{-}1,
```

where label1 and label2 are different strings (can be a zero-length strings) that are defined by a specific protocol (see, for example, TLS 1.3 updating traffic keys algorithm [TLSDraft]).

5. Internal Re-keying Mechanisms

This section presents an approach to increase the lifetime of negotiated key by re-keying during each separate message processing. It provides an internal re-keying mechanisms called ACPKM and ACPKM-Master that do not use and use a master key respectively. Such mechanisms are integrated into the base modes of operations and can be considered as the base mode extensions, therefore they are called "internal re-keying" in this document.

5.1. Constructions that Do Not Require Master Key

This section describes the block cipher modes that uses the ACPKM re-keying mechanism (described in Section 5.1.1), which does not use master key: an initial key is used directly for the encryption of the data.

5.1.1. ACPKM Re-keying Mechanisms

This section defines periodical key transformation with no master key which is called ACPKM re-keying mechanism. This mechanism can be applied to one of the basic encryption modes (CTR and GCM block cipher modes) for getting an extension of this encryption mode that uses periodical key transformation with no master key. This extension can be considered as a new encryption mode.

An additional parameter that defines the functioning of basic encryption modes with the ACPKM re-keying mechanism is the section size N. The value of N is measured in bits and is fixed within a specific protocol

based on the requirements of the system capacity and key lifetime (some recommendations on choosing N will be provided in Section 7). The section size N MUST be divisible by the block size n.

The main idea behind internal re-keying with no master key is presented in Fig.3:

```
Lifetime of a key = L,
section size = const = N,
maximum message size = m_max.
          ACPKM ACPKM ACPKM
      K^1 = K ---> K^2 ---...> K^{I max-1} ----> K^{I max}
                            Message(1) |========|======| ... |=======|=====: |
Message(2) |========| ... |=== | : |
                              : :
Message(q) |========| ... |=======| : |
            section
           <---->
                            m max
             N bit
I_max = ceil(m_max/N),
q*N \leftarrow L.
          Figure 3: Key meshing with no master key
```

During the processing of the input message M with the length m in some encryption mode that uses ACPKM key transformation of the key K the message is divided into I = ceil(m/N) parts (denoted as M = M_1 | M_2 | ... | M_I, where M_i is in V_N for i = 1, 2, ..., I-1 and M_I is in V_r, r <= N). The first section is processed with the initial key K^1 = K. To process the (i+1)-th section the K^{i+1} key value is calculated using ACPKM transformation as follows:

```
K^{i+1} = ACPKM(K^i) = MSB_k(E_{K^i}(W_1) \mid ... \mid E_{K^i}(W_J)),
```

where J = ceil(k/n), $W_t = phi_c(D_t)$ for any t in $\{1, ..., J\}$ and $D_1, D_2, ..., D_J$ are in V_n and are calculated as follows:

```
D_1 \mid D_2 \mid ... \mid D_J = MSB_{J^*n}(D),
```

where D is the following constant in V_{1024}:

```
D = (F3 | 74 | E9 | 23 | FE | AA | D6 | DD

| 98 | B4 | B6 | 3D | 57 | 8B | 35 | AC

| A9 | 0F | D7 | 31 | E4 | 1D | 64 | 5E

| 22 | C0 | 6C | E2 | 4A | C7 | FB | 5B).
```

N o t e : The constant D is such that $phi_c(D_1)$, ..., $phi_c(D_J)$ are pairwise different for any allowed n, k, c values.

N o t e: The constant D is such that D = $sha512(streebog512(0^1024)) \mid sha512(streebog512(1^1024))$, where sha512 is a hash function with 512-bit output corresponding to the algorithm SHA-512 [SHA-512], streebog512 is a hash function with 512-bit output, corresponding to the algorithm GOST R 34.11-2012 [GOST3411-2012], [RFC6986].

5.1.2. CTR-ACPKM Encryption Mode

This section defines a CTR-ACPKM encryption mode that uses internal ACPKM re-keying mechanism for the periodical key transformation.

The CTR-ACPKM mode can be considered as the extended by the ACPKM re-keying mechanism basic encryption mode CTR (see [MODES]).

The CTR-ACPKM encryption mode can be used with the following parameters:

- 64 <= n <= 512;
- 128 <= k <= 512;
- the number of bits c in a specific part of the block to be incremented is such that 32 <= c <= 3/4 n.

The CTR-ACPKM mode encryption and decryption procedures are defined as follows:

```
CTR-ACPKM-Encrypt(N, K, ICN, P)
| Input:
| - Section size N,
| - key K,
| - initial counter nonce ICN in V_{n-c},
| - plaintext P = P_1 | ... | P_b, |P| < n * 2^{c-1}.
| Output:
- Ciphertext C.
|-----|
| 1. CTR_1 = ICN | 0^c
| 2. For j = 2, 3, ..., b do
      CTR_{j} = Inc_c(CTR_{j-1})
| 3. K<sup>1</sup> = K
| 4. For i = 2, 3, ..., ceil(|P|/N)
      K^i = ACPKM(K^{i-1})
| 5. For j = 1, 2, ..., b do
    i = ceil(j*n / N),
     G_j = E_{K^i}(CTR_j)
| 6. C = P (xor) MSB_{| P | G_1 | ... | G_b}
```

The initial counter nonce ICN value for each message that is encrypted under the given key must be chosen in a unique manner.

The message size m MUST NOT exceed n * 2^{c-1} bits.

5.1.3. GCM-ACPKM Encryption Mode

This section defines a GCM-ACPKM encryption mode that uses internal ACPKM re-keying mechanism for the periodical key transformation.

The GCM-ACPKM mode can be considered as the extended by the ACPKM re-keying mechanism basic encryption mode GCM (see [GCM]).

The GCM-ACPKM encryption mode can be used with the following parameters:

- n in {128, 256};
- 128 <= k <= 512;
- the number of bits c in a specific part of the block to be incremented is such that 32 <= c <= 3/4 n;
- authentication tag length t.

The GCM-ACPKM mode encryption and decryption procedures are defined as follows:

```
GCTR(N, K, ICB, X)
| Input:
| - Section size N,
| - key K,
| - initial counter block ICB,
| -X = X_1 | ... | X_b, X_i \text{ in } V_n \text{ for } i = 1, ..., b-1 \text{ and }
                   X_b in V_r, where r <= n.
| Output:
| - Y in V_{|X|}.
1. If X in V_0 then return Y, where Y in V_0
| 2. GCTR_1 = ICB
| 3. \text{ For } i = 2, ..., b do
       GCTR_i = Inc_c(GCTR_{i-1})
4. K^1 = K
| 5. For j = 2, ..., ceil(I*n / N)
       K^{j} = ACPKM(K^{j-1})
| 6. \text{ For } i = 1, \dots, b \text{ do}
      j = ceil(i*n / N),
       G_i = E_{K_j}(GCTR_i)
| 7. Y = X (xor) MSB_{[X]}(G_1 | ... | G_b)
8. Return Y.
GCM-ACPKM-Encrypt(N, K, IV, P, A)
| Input:
| - Section size N,
| - key K,
| - initial counter nonce ICN in V_{n-c},
| - plaintext P, |P| \le n^*(2^{c-1} - 2), P = P_1 | ... | P_b,
| - additional authenticated data A.
| Output:
| - Ciphertext C,
| - authentication tag T.
| 1. H = E_{K}(0^n)
| 2. If c = 32, then ICB 0 = ICN | 0^31 | 1
    if c!=32, then s=n * ceil(|ICN| / n) - |ICN|,
            ICB_0 = GHASH(ICN \mid 0^{s+n-64} \mid Vec_64(|ICN|), H) \mid
| 3. C = GCTR(N, K, Inc_32(ICB_0), P)
| 4. u = n*ceil(|C| / n) - |C| | | | |
| v = n*ceil(|A| / n) - |A|
| 5. S = GHASH(A | 0^v | C | 0^u | 0^{n-128} | Vec_64(|A|) |
           | Vec_64(|C|), H)
| 6. T = MSB_t(E_{K}(ICB_0) (xor) S)
| 7. Return C | T
```

```
GCM-ACPKM-Decrypt(N, K, IV, A, C, T)
| Input:
| - Section size N,
| - key K,
| - initial counter block ICB,
- additional authenticated data A.
| - ciphertext C, |C| <= n*(2^{c-1} - 2), C = C_1 | ... | C_b,
| - authentication tag T
| Output:
I - Plaintext P or FAIL.
| 1. H = E_{K}(0^n)
2. If c = 32, then ICB_0 = ICN | 0^31 | 1
   if c!=32, then s=n^*ceil(|ICN|/n)-|ICN|,
           ICB_0 = GHASH(ICN \mid 0^{s+n-64} \mid Vec_64(|ICN|), H)
| 3. P = GCTR(N, K, Inc_32(ICB_0), C)
| 4. u = n*ceil(|C| / n)-|C|
   v = n*ceil(|A| / n)-|A|
| 5. S = GHASH(A | 0^v | C | 0^u | 0^{n-128} | Vec_64(|A|) |
          | Vec_64(|C|), H)
| 6. T' = MSB_t(E_{K}(ICB_0) (xor) S)
| 7. If T = T' then return P; else return FAIL
```

The * operation on (pairs of) the 2ⁿ possible blocks corresponds to the multiplication operation for the binary Galois (finite) field of 2ⁿ elements defined by the polynomial f as follows (by analogy with [GCM]):

```
n = 128:

f = a^128 + a^7 + a^2 + a^1 + 1.

n = 256:

f = a^256 + a^10 + a^5 + a^2 + 1.
```

The initial vector IV value for each message that is encrypted under the given key must be chosen in a unique manner.

The message size m MUST NOT exceed n*(2^{c-1} - 2) bits.

The key for computing values E {K}(ICB 0) and H is not updated and is equal to the initial key K.

5.2. Constructions that Require Master Key

This section describes the block cipher modes that uses the ACPKM-Master re-keying mechanism (described in Section 5.2.1), which use the initial key K as a master key K*, so K is never used directly for the data processing but is used for key derivation.

5.2.1. ACPKM-Master Key Generation from the Master Key

This section defines periodical key transformation with master key K* which is called ACPKM-Master rekeying mechanism. This mechanism can be applied to one of the basic encryption modes (CTR, GCM, CBC, CFB, OFB, OMAC encryption modes) for getting an extension of this encryption mode that uses periodical key transformation with master key. This extension can be considered as a new encryption mode.

Additional parameters that defines the functioning of basic encryption modes with the ACPKM-Master re-

keying mechanism are the section size N and change frequency T* of the key K*. The values of N and T* are measured in bits and are fixed within a specific protocol based on the requirements of the system capacity and key lifetime (some recommendations on choosing N and T* will be provided in Section 7). The section size N MUST be divisible by the block size n. The key frequency T* MUST be divisible by n.

The main idea behind internal re-keying with master key is presented in Fig.4:

```
Lifetime of a key = L,
change frequency T*,
section size N,
maximum message size = m max.
             ACPKM ACPKM
       K^*_1 = K^*_{----} K^*_2 ---- K^*_1 \max
                V ... V
                           V ... V
      K[1] K[t]
               K[t+1] K[2t] K[(l_max-1)t+1] K[l_max*t]
               1 1
               V
                            V
| | : ||
               Message(q)||=======|...|======||==== |...| ||...||
    section
    <---->
     N bit
                                m_max
|K[i]| = d
t = T^*/d
I_max = ceil(m_max/N),
q*N <= L.
       Figure 4: Key meshing with master key
```

During the processing of the input message M with the length m in some encryption mode that uses ACPKM-Master key transformation with the master key K^* and key frequency T^* the message M is divided into I = ceil(m/N) parts (denoted as $M = M_1 \mid M_2 \mid ... \mid M_l$, where M_i is in V_N for i in $\{1, 2, ..., l-1\}$ and M_l is in V_r , $r \in N$). The j-th section is processed with the key material K[j], K[j] = d, that has been calculated with the ACPKM-Master algorithm as follows:

```
IV = 1^{n/2},

K[1] \mid ... \mid K[I] = ACPKM-Master(T^*, K^*, d^*I) = CTR-ACPKM-Encrypt (T^*, K^*, IV, 0^{d^*I}).
```

5.2.2. CTR Mode Key Meshing

This section defines a CTR-ACPKM-Master encryption mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The CTR-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic encryption mode CTR (see [MODES]).

The CTR-ACPKM-Master encryption mode can be used with the following parameters:

- 64 <= n <= 512;
- 128 <= k <= 512;
- the number of bits c in a specific part of the block to be incremented is such that 32 <= c <= 3/4 n.

The key material K[j] that is used for one section processing is equal to $K^{*}[j] = k$ bits.

The CTR-ACPKM-Master mode encryption and decryption procedures are defined as follows:

```
CTR-ACPKM-Master-Encrypt(N, K*, T*, ICN, P)
| Input:
| - Section size N,
- master key K*,
| - change frequency T*,
- initial counter nonce ICN in V_{n-c},
| - plaintext P = P_1 | ... | P_b, |P| \le 2^{n/2-1}^n N / k.
| Output:
| - Ciphertext C.
|-----
| 1. CTR 1 = ICN | 0<sup>c</sup>
| 2. For j = 2, 3, ..., b do
     CTR_{j} = Inc_c(CTR_{j-1})
| 3. I = ceil(b*n / N)
| 4. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 5. For j = 1, 2, ... , b do
     i = ceil(j*n / N),
      G_j = E_{K^i}(CTR_j)
| 6. C = P (xor) MSB_{|P|}(G_1 | ... |G_b)
| 7. Return C
| CTR-ACPKM-Master-Decrypt(N, K*, T*, ICN, C)
| Input:
| - Section size N,
- master key K*,
| - change frequency T*,
| - initial counter nonce ICN in V_{n-c},
| - ciphertext C = C_1 | ... | C_b, |C| \le 2^{n/2-1}^n N / k. |
| Output:
| - Plaintext P.
1. Return CTR-ACPKM-Master-Encrypt(N, K*, T*, ICN, C)
```

The initial counter nonce ICN value for each message that is encrypted under the given key must be chosen

in a unique manner. The counter (CTR_{i+1}) value does not change during key transformation.

The message size m MUST NOT exceed (2^{n/2-1}*n*N / k) bits.

5.2.3. GCM Mode Key Meshing

This section defines a GCM-ACPKM-Master encryption mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The GCM-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic encryption mode GCM (see [GCM]).

The GCM-ACPKM-Master encryption mode can be used with the following parameters:

- n in {128, 256};
- 128 <= k <= 512;
- the number of bits c in a specific part of the block to be incremented is such that 32 <= c <= 3/4 n;
- authentication tag length t.

The key material K[j] that is used for one section processing is equal to $K^{*}j$, $|K^{*}j| = k$ bits, that is calculated as follows:

$$K^1 | ... | K^j | ... | K^l = ACPKM-Master(T^*, K^*, k^l).$$

The GCM-ACPKM-Master mode encryption and decryption procedures are defined as follows:

```
| GHASH(X, H)
| - Bit string X = X_1 | ... | X_m, X_i \text{ in } V_n \text{ for } i \text{ in } \{1, ..., m\}
| Output:
- Block GHASH(X, H) in V_n
|-----|
| 1. Y 0 = 0^n
| 2. For i = 1, ... , m do
    Y_i = (Y_{i-1} (xor) X_i)^*H
3. Return Y m
| GCTR(N, K*, T*, ICB, X)
| - Section size N,
- master key K*,
| - change frequency T*,
| - initial counter block ICB,
| -X = X_1 | ... | X_b, X_i \text{ in } V_n \text{ for } i = 1, ..., b-1 \text{ and } i
           X b in V r, where r \le n.
| Output:
                                                  | - Y in V_{|X|}.
| 1. If X in V_0 then return Y, where Y in V_0
| 2. GCTR_1 = ICB
```

```
| 3. For i = 2, ..., b do
       GCTR_i = Inc_c(GCTR_{i-1})
| 4. I = ceil(b*n / N)
| 5. K^1 | ... | K^l = ACPKM-Master(T*, K*, k*l)
| 6. \text{ For } j = 1, \dots, b \text{ do}
      i = ceil(j*n / N),
      G_j = E_{K^i}(GCTR_j)
| 7. Y = X (xor) MSB_{[X]}(G_1 | ... | G_b)
8. Return Y
GCM-ACPKM-Master-Encrypt(N, K*, T*, IV, P, A)
| Input:
| - Section size N,
| - master key K*,
| - change frequency T*,
| - initial counter nonce ICN in V_{n-c},
| - plaintext P, |P| \le n*(2^{c-1} - 2).
| - additional authenticated data A.
| Output:
| - Ciphertext C,
| - authentication tag T.
\mid 1. K<sup>1</sup> = ACPKM-Master(T*, K*, k)
| 2. H = E_{K^1}(0^n)
| 3. If c = 32, then ICB_0 = ICN | 0^31 | 1
   if c!=32, then s=n^*ceil(|ICN|/n) - |ICN|,
            ICB_0 = GHASH(ICN | 0^{s+n-64} | Vec_64(|ICN|), H) |
| 4. C = GCTR(N, K^*, T^*, Inc_32(J_0), P) |
| 5. u = n*ceil(|C| / n) - |C| | | | |
| v = n*ceil(|A| / n) - |A|
| 6. S = GHASH(A | 0^v | C | 0^u | 0^{n-128} | Vec_64(|A|) |
           | Vec_64(|C|), H)
| 7. T = MSB_t(E_{K^1}(J_0) (xor) S)
| 8. Return C | T
GCM-ACPKM-Master-Decrypt(N, K*, T*, IV, A, C, T)
| Input:
| - Section size N,
| - master key K*,
| - change frequency T*,
| - initial counter nonce ICN in V {n-c},
| - additional authenticated data A.
| - ciphertext C, |C| <= n*(2^{c-1} - 2),
| - authentication tag T,
| Output:
| - Plaintext P or FAIL.
```

The * operation on (pairs of) the 2ⁿ possible blocks corresponds to the multiplication operation for the binary Galois (finite) field of 2ⁿ elements defined by the polynomial f as follows (by analogy with [GCM]):

```
n = 128:

f = a^128 + a^7 + a^2 + a^1 + 1.

n = 256:

f = a^256 + a^10 + a^5 + a^2 + 1.
```

The initial vector IV value for each message that is encrypted under the given key must be chosen in a unique manner.

The message size m MUST NOT exceed $(2^{n/2-1}^n N / k)$ bits.

5.2.4. CBC Mode Key Meshing

This section defines a CBC-ACPKM-Master encryption mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The CBC-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic encryption mode CBC (see [MODES]).

The CBC-ACPKM-Master encryption mode can be used with the following parameters:

- 64 <= n <= 512;
- 128 <= k <= 512.

In the specification of the CBC-ACPKM-Master mode the plaintext and ciphertext must be a sequence of one or more complete data blocks. If the data string to be encrypted does not initially satisfy this property, then it MUST be padded to form complete data blocks. The padding methods are outside the scope of this document. An example of a padding method can be found in Appendix A of [MODES].

The key material K[i] that is used for one section processing is equal to K^{i} , K^{i} = k bits.

We will denote by D {K} the decryption function which is a permutation inverse to the E {K}.

The CBC-ACPKM-Master mode encryption and decryption procedures are defined as follows:

```
+-----+
| CBC-ACPKM-Master-Encrypt(N, K*, T*, IV, P) |
|-------|
| Input:
```

```
| - Section size N,
| - master key K*,
| - change frequency T*,
| - initialization vector IV in V_n,
| - plaintext P = P_1 | ... | P_b, |P| <= 2^{n/2-1}*n*N / k, |
            |P_b| = n.
| Output:
| - Ciphertext C.
|-----
| 1. I = ceil(b*n/N)
| 2. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 3. C_0 = IV
| 4. \text{ For } j = 1, 2, ..., b \text{ do}
     i = ceil(j*n / N),
      C_j = E_{K^i}(P_j (xor) C_{j-1})
| 5. Return C = C_1 | ... | C_b
| CBC-ACPKM-Master-Decrypt(N, K*, T*, IV, C)
| Input:
| - Section size N,
- master key K*,
| - change frequency T*,
| - initialization vector IV in V_n,
| - ciphertext C = C_1 | ... | C_b, |C| \le 2^{n/2-1}*n*N/k,
            |C_b| = n.
| Output:
| - Plaintext P.
|-----
| 1. | = ceil(b*n / N)
| 2. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 3. C_0 = IV
| 4. \text{ For } j = 1, 2, ..., b \text{ do}
     i = ceil(j*n/N)
      P_j = D_{K^i}(C_j) (xor) C_{j-1}
| 5. Return P = P_1 | ... | P_b
```

The initialization vector IV for each message that is encrypted under the given key need not to be secret, but must be unpredictable.

The message size m MUST NOT exceed $(2^{n/2-1}*n*N / k)$ bits.

5.2.5. CFB Mode Key Meshing

This section defines a CFB-ACPKM-Master encryption mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The CFB-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic encryption mode CFB (see [MODES]).

The CFB-ACPKM-Master encryption mode can be used with the following parameters:

- 64 <= n <= 512;
- 128 <= k <= 512.

The key material K[i] that is used for one section processing is equal to K^{i} , $|K^{i}| = k$ bits.

The CFB-ACPKM-Master mode encryption and decryption procedures are defined as follows:

```
| CFB-ACPKM-Master-Encrypt(N, K*, T*, IV, P)
| Input:
| - Section size N,
| - master key K*,
| - change frequency T*,
| - initialization vector IV in V_n,
| - plaintext P = P_1 | ... | P_b, |P| \le 2^{n/2-1}^n N / k. |
| Output:
| - Ciphertext C.
|-----|
| 1. l = ceil(b*n / N)
2. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 3. C_0 = IV
| 4. \text{ For } j = 1, 2, ..., b do
      i = ceil(j*n / N)
      C_j = E_{K^i}(C_{j-1}) (xor) P_j
| 5. Return C = C_1 | ... | C_b.
CFB-ACPKM-Master-Decrypt(N, K*, T*, IV, C#)
| Input:
| - Section size N,
- master key K*,
| - change frequency T*,
| - initialization vector IV in V_n,
| - ciphertext C = C_1 | ... | C_b, |C| \le 2^{n/2-1}^nN / k. |
| Output:
| - Plaintext P.
|-----|
| 1. l = ceil(b*n / N)
| 2. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 3. C 0 = IV
| 4. \text{ For } j = 1, 2, ..., b do
     i = ceil(j*n / N),
      P_j = E_{K^i}(C_{j-1}) (xor) C_j
| 5. Return P = P_1 | ... | P_b
```

The initialization vector IV for each message that is encrypted under the given key need not to be secret, but must be unpredictable.

The message size m MUST NOT exceed 2^{n/2-1}*n*N/k bits.

5.2.6. OFB Mode Key Meshing

This section defines an OFB-ACPKM-Master encryption mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The OFB-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic encryption mode OFB (see [MODES]).

The OFB-ACPKM-Master encryption mode can be used with the following parameters:

- 64 <= n <= 512;
- 128 <= k <= 512.

The key material K[j] used for one section processing is equal to $K^{*}[j] = k$ bits.

The OFB-ACPKM-Master mode encryption and decryption procedures are defined as follows:

```
| OFB-ACPKM-Master-Encrypt(N, K*, T*, IV, P)
| Input:
| - Section size N,
| - master key K*,
| - change frequency T*,
| - initialization vector IV in V n,
| - plaintext P = P_1 | ... | P_b, |P| \le 2^{n/2-1}^n N / k.
| Output:
| - Ciphertext C.
|-----|
1. l = ceil(b*n / N)
| 2. K^1 | ... | K^I = ACPKM-Master(T*, K*, k*I)
| 3. G_0 = IV
| 4. \text{ For } j = 1, 2, ..., b do
     i = ceil(j*n / N),
      G_{j} = E_{K_{i}}(G_{j-1})
| 5. Return C = P (xor) MSB_{|P|}(G_1 | ... | G_b)
OFB-ACPKM-Master-Decrypt(N, K*, T*, IV, C)
| Input:
| - Section size N,
- master key K*,
| - change frequency T*,
| - initialization vector IV in V n,
| - ciphertext C = C_1 | ... | C_b, |C| <= 2^{n/2-1}*n*N / k. |
| Output:
| - Plaintext P.
1. Return OFB-ACPKM-Master-Encrypt(N, K*, T*, IV, C)
```

The initialization vector IV for each message that is encrypted under the given key need not be unpredictable, but it must be a nonce that is unique to each execution of the encryption operation.

The message size m MUST NOT exceed 2^{n/2-1}*n*N / k bits.

5.2.7. OMAC Mode Key Meshing

This section defines an OMAC-ACPKM-Master message authentication code calculation mode that uses internal ACPKM-Master re-keying mechanism for the periodical key transformation.

The OMAC-ACPKM-Master encryption mode can be considered as the extended by the ACPKM-Master rekeying mechanism basic message authentication code calculation mode OMAC (see [RFC4493]).

The OMAC-ACPKM-Master message authentication code calculation mode can be used with the following parameters:

- n in {64, 128, 256};
- 128 <= k <= 512.

The key material K[j] that is used for one section processing is equal to $K^j \mid K^j_1$, where $|K^j| = k$ and $|K^j_1| = n$.

The following is a specification of the subkey generation process of OMAC:

Where R_n takes the following values:

- n = 64: $R_{64} = 0^{59} | 11011$;
- n = 128: $R_{128} = 0^{120} | 10000111$;
- n = 256: $R_{256} = 0^{145} | 10000100101$.

The OMAC-ACPKM-Master message authentication code calculation mode is defined as follows:

```
| - Section size N,
| - master key K*,
| - key frequency T*,
| - plaintext M = M_1 | ... | M_b, |M| <= 2^{n/2}*n^2*N / (k + n). |
| Output:
| - message authentication code T.
| 1. C 0 = 0^n
| 2. I = ceil(b*n / N)
3. K^1 | K^1_1 | ... | K^I | K^I_1 = ACPKM-Master(T*, K*, (k+n)*I) |
| 4. \text{ For } j = 1, 2, ..., b-1 \text{ do}
       i = ceil(j*n / N),
       C_j = E_{K^i}(M_j(xor) C_{j-1})
| 5. [K] = Generate\_Subkey(K^I_1, |M_b|)
| 6. \text{ If } | M_b| = n \text{ then } M^*_b = M_b
              else M^*_b = M_b | 1 | 0^{n - 1 - |M_b|}
| 7. T = E_{K^{l}}(M^{*}_{b}(xor) C_{b-1}(xor) [K])
8. Return T
```

The message size m MUST NOT exceed $2^{n/2}n^2 N / (k + n)$ bits.

6. Joint Usage of External and Internal Re-keying

Any mechanism described in Section 4 can be used with any mechanism described in Section 5.

7. Security Considerations

7.1. Principles of Choice of Constructions and Security Parameters

External re-keying mechanism is RECOMMENDED to be used in protocols that process pretty small messages (e.g. TLS).

Internal re-keying mechanism is RECOMMENDED to be used in protocols that can process large messages (e.g. IPSec).

For the protocols that process messages of different lengths it is RECOMMENDED to use joint methods described in Section 6.

7.2. Requirements For Base Primitives

Re-keying should be used to increase "a priori" security properties of ciphers in hoslile environments (e.g. with side-channel adversaries). If some non-negligible attacks are known for a cipher, it MUST NOT be used. So re-keying can not be used as a patch for vulnerable ciphers. Base cipher properties must be well analyzed, because security of re-keying mechanisms is based on security of a block cipher as a pseudorandom function.
