

RSVP Aggregation

Limit scheduler state in domain B

Limit RSVP control state in domain B

Draft-guerin-aggreg-rsvp-00.txt

Draft-berson-rsvp-aggregation-00.ps

Requirements

(in aggregated domains)

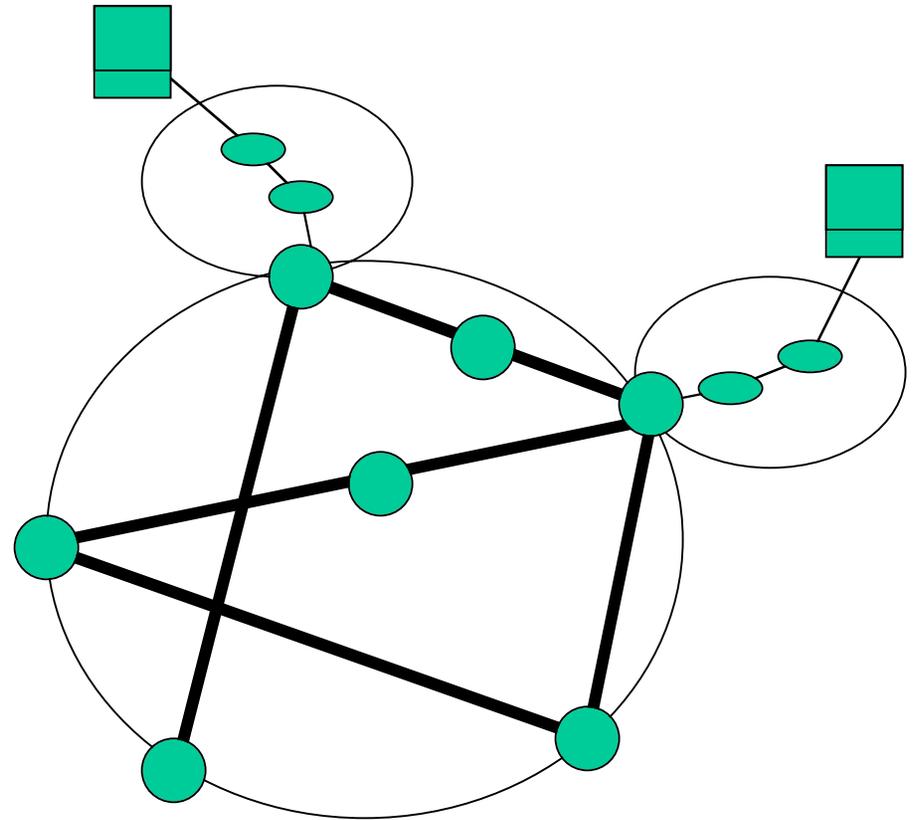

- No (limited) awareness of individual RSVP flows
 - Scheduling state
 - RSVP state
- Must satisfy QoS requirements of individual flows
 - Delivered service
 - Path characterization (ADSPEC)
- Must maintain isolation of flows
 - Nonconformant traffic of one flow must not zap others
- Must not limit ability to support individual flow reservations in other domains
 - Particularly, must be able to un-aggregate

Draft-guerin...

- Document space
 - Survey - range of possibilities
 - Assumes unicast
 - Covers full spectrum of issues
 - RSVP state management
 - Aggregate scheduling requirements (briefly)
 - Admission control
 - Path characterization
 - All services

Tunneling Approach

- Point-to-point RSVP tunnels between ingress and egress routers of the aggregated domain
- End-to-end QoS data and RSVP messages tunnel through domain

Tunneling

- Ingress, egress routers do RSVP for aggregate pipe resources
 - Egress routers adjust reservations for flow arrival/departure and routing changes
 - Individual PATH adspecs updated by egress based on cached aggregate PATH adspec
- Drawbacks
 - Difficulty maintaining isolation of individual flows
 - If using same service, must send nonconformant traffic outside the tunnel
 - Encap/decap/data overhead

Tag-based aggregation

- Approach

- Scheduling class in core of net selected by packet tag set at ingress
- Class selected based on reservation request
- Individual RSVP messages sent through domain transparently
- Individual PATH messages (adspec) updated at egress

- Issues

- Definition of appropriate scheduling behavior for aggregated flows
- Transparent location of flow egress/ingress points
- (Dynamic) allocation of backbone resources
- Computation of adspec information

Class-based RSVP approach

Ingress Router

Forwards “hidden” PATH msgs into cloud.

Sends “regular” PATH message directly to egress (for aggregate reservation)

Egress Router

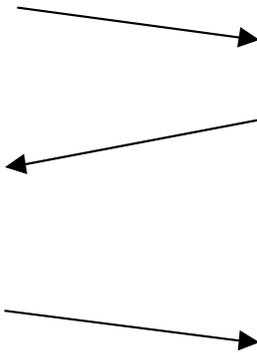

Receives “hidden” PATH msg.
Notifies ingress (PHOP) of existence.

Receives aggregate PATH, can now compute ADSPECs. Now unhides and forwards individual PATH msgs

Add flow in individual RESV to list of flows that are tagged for special forwarding.

Receives RESV msg from new flow.

- Create or update reservation for aggregate path (RESV to ingress).
- Send individual RESV messages directly to ingress

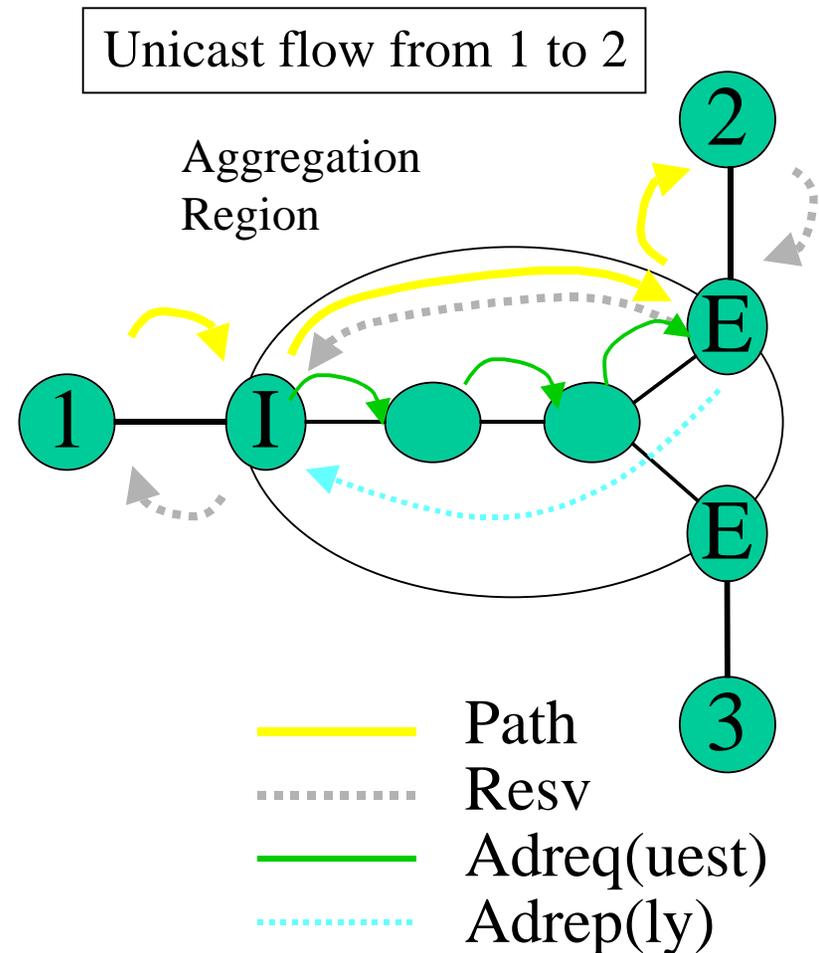

Draft-berson...

- Document space
 - Unicast and multicast
 - Controlled-load like services
 - Assumes measurement-based admission control
 - Does not explicitly discuss adspec/characterization issues
 - Primary focus on RSVP / signalling

Berson - unicast

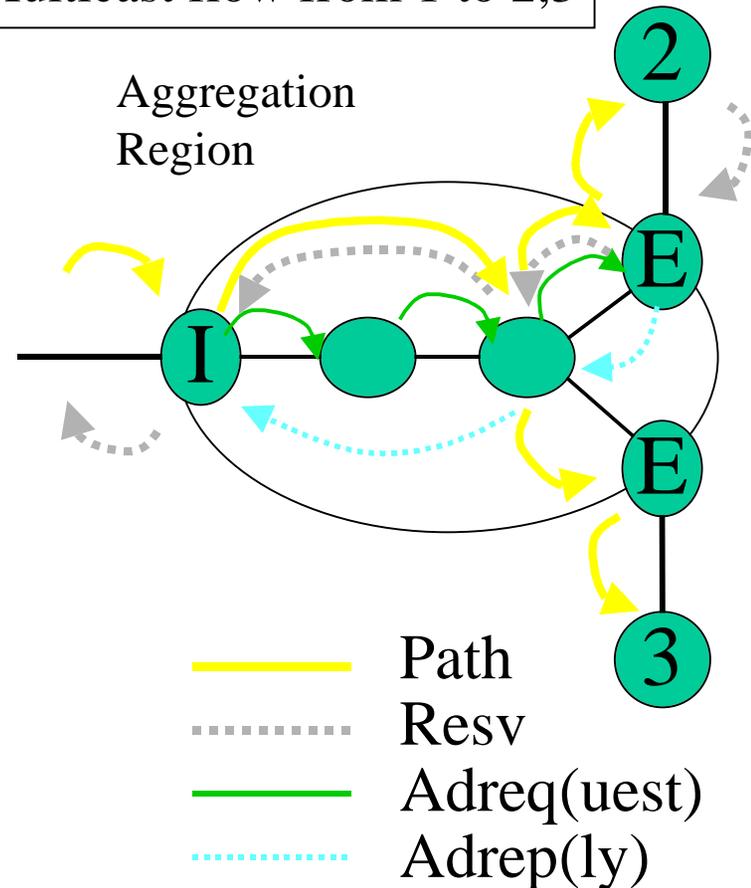

- Flows scheduled as aggregated traffic classes in the region
- Retains hop-by-hop per-path admission control
- Packets are tagged with class by ingress router
- Interior routers ignore normal RSVP messages (RSVP “off”)
- Arrival of RESV at region ingress triggers hop-by-hop admission control along data path (Adreq)
- Collected result returned to ingress router (Adrep) – starts tagging packets if reservation accepted

Berson - multicast

- Multicast flows require some state within the region
 - Heterogeneous reservations
 - Qos and best-effort branches
- Creation of split point “wakes up” RSVP session
 - Next PATH message creates RSVP state. Router installs “retagger” to remark packets leaving reserved path to new QoS
- Admission control done over homogeneous reservation segments
 - Newly awake router becomes endpoint for adreq/adrep msgs

Multicast flow from 1 to 2,3

Comments

- Both of these drafts assume per-path dynamic management of aggregate resources
- Both suggest small changes to RSVP
- Neither creates a clear and shining line between “outer” RSVP and “inner” mechanism
 - But both are close
 - Some efficiency gained by lack of complete separation
- Consider these ideas as tools in a toolkit
 - Look for a clean functional interface
 - That can support these and other techniques
